

Domain-Incremental Learning (DIL) — One Unified Schema, Shifting Domains

Shared label space $L = \{ \text{HEADER, KEY, VALUE, OTHER} \} (+ O \text{ background})$ — fixed for all sessions; only the input domain changes

Training sequence FUNSD → SROIE → CORD orders the domains by increasing distance from the canonical form schema. The label space L is **fixed**; only the input distribution $P_t(X)$ shifts at each session boundary.

Caveat: KEY is sparse outside FUNSD — COMPANY is the only KEY-like field in SROIE, and CORD has no KEY at all (recorded as a known limitation).
